The first trial of the method began in the spring, and it ran from 1996 to 2004 in three clinics. Each clinic measured the same teeth with a gauge that reads to 0.5 mm, and the mean depth was 2.5 mm at the start of the trial. The team counted 120 patients in the first year and 340 patients in the last year. Class II cavities were the most common finding, and Class IV cavities were rare. The report has two short lists of findings.

1. The depth did not change in the first two years.
2. The depth became less after the change of method.

The text after the list goes on as a normal paragraph. It has no numbers at the start of its lines, so the reader must keep it as one paragraph and must not cut it into pieces at each line end.
